Update: Some of the example tests on this page no longer work (I don't have a Facebook account anymore and the Twitter URL I used went offline). The technique it's self is still alive and relevant though.

When you visit my website, I can automatically and silently determine if you're logged into [Facebook](#), [Twitter](#), [GMail](#) and [Digg](#). There are almost certainly thousands of other sites with this issue too, but I picked a few vulnerable well known ones to get your attention. You may not care that I can tell you're logged into GMail, but would you care if I could tell you're logged into one or more porn or warez sites? Perhaps <http://oppressive-regime.example.org/> would like to collect a list of their users who are logged into <http://controversial-website.example.com/>?

Ignoring the privacy implications for a second, as a website developer, you might like to know if your visitors are logged into GMail; you could use that information to automatically fill the email fields in your forms with "@gmail.com"... Perhaps you might want to make your Facebook "like" buttons more prominent if you can tell your visitor is logged into Facebook at the moment? Here's how I achieve this: First of all. Lets check if you're logged into GMail right now (this check is disabled)... Now, how did I get that information? Really, really, easily... I generated a hidden image in my HTML similar to this:

```
</script>

<script type="text/javascript"
src="https://www.facebook.com/imike3"
onload="logged_in_to_facebook()"
onerror="not_logged_in_to_facebook()"
async="async"></script>
```

In Firefox, Safari and Chrome, the script tags fire onload if a 200 HTTP status code is returned, even if there was no valid JavaScript and the Content-Type was text/html. But if the status code was one of 404,

403, 406 or 500, then an error is triggered instead. In the above examples, the Twitter URL returns an error code if you're logged in, but redirects to the login form with a success status code if you're not logged in. The Facebook one works because my profile is only visible to people who are logged in and returns a 404 if you're not. There is a similar problem with Digg. <https://digg.com/settings> returns a 403 status code if you're not logged in, but a 200 if you are.

This can be an awkward problem to avoid if you're developing a website. Some of these requests could be stopped by doing referrer checks; reject all external referrers for content only accessible when logged in. You want your status codes and responses to image requests to be relevant, but that can leak information. Firefox users could defend from this problem by using the [Request Policy](#) addon. I've never used it myself because it looks like a pain to manage, but it sounds like it would do the job.

And finally, this isn't just an issue of detecting whether or not a user is logged in. The question could technically be anything, if a HTTP response results in an image or html depending on the answer, or results in a success/error status code depending on the answer.

For the web developers out there who are familiar with jQuery, as a demonstration of the usefulness of this technique. The following chunk of code will detect if a user is logged into GMail, and if they are will replace all the mailto: links on your webpage with links to the GMail compose window (automatically filling in the To field): [Like this article](#)

```
$('#<img/>').hide().attr('src',
  'https://mail.google.com/mail/photos/img/photos/public/AIbEiAIAABDCKa_hYq24u2WUyILdmNhcmRfcGhvdG8q
').load(function(){
  $('a[href^="mailto:"]').each(function(){
    var email = $(this).attr('href').replace(/^mailto:/, '');
    $(this).attr('href',
      'https://mail.google.com/mail/?view=cm&fs=1&tf=0&to='+escape(email)
    );
  });
}).appendTo('body');
```
