In this week's bonus footage of HackerKast, I showed Matt my new JavaScript port scanning magic that I dubbed "Canadian Beacon" because it uses the new Beacon API. It was either that or Kevin Beacon – I had to make a tough choice with my puns. It utilizes both the performance API and the beacon API. It shows how you can use iframes and performance APIs to do basically the same thing we used to be able to do with onload event handlers on iframes of yester-year. Not a huge deal, because we can do this in a bunch of different ways already, but it shows how easy it is to do JavaScript port scanning; and even if someone bothers to shut one variant down, this and other variants will take their place. This is one of the major reasons [Aviator](#) has chosen to break access to RFC1918 from the Internet. Only a few browser variants are vulnerable, Chrome and apparently Firefox though I only got it working in Chrome. If you want to see a demo you can [check out Canadian Beacon here](#).
