[[2012-11-25]]() { [what's real and what's not](#) }

Some days back i read [this](#) post which is about Browser Event Hijacking, in my eyes a cool way to get some interesting information. I tried to rebuild it like the author did it back in the post but with a fake list of leaked passwords. So someone just presses CTRL+F in his browser and types his password to look if it is leaked. I think this is pretty normal behavior (I do it this way). But obviously this is not such a great idea.

```
$(window).keydown(function(evt){
    if((evt.which == "70" && ( evt.metaKey || evt.ctrlKey ))){
        evt.preventDefault();
        /* display fake search */
    }
});
```

Not the browsers search bar will popup and wait for your input but a fake one will appear and steal all your search strings. This happens because of [preventDefault\(\)](#)**

"Description: If this method is called, the default action of the event will not be triggered."

My goal was to build a fake search bar which automatically inserts your search string to the leaked password list and highlights it like the regular would do it. That wasn't pretty tough but even more so to display some good and legitimate looking search result stats. I gave up on that, the freaking stats are now just random. The code is awful, I'm not very proud of it. You can look at the result [here](#). It would be so badass if someone would code it for all browsers and make it look 100% legit. Once again you have to look carefully if you walk the intertubez. "What's real and what's not" sometimes even affects your browser itself.
